├── adapters/
│   ├── windows/                 # Windows-specific implementations
│   ├── linux/                   # Linux-specific implementations
│   ├── macos/                   # macOS-specific implementations
│   └── mobile/                  # Android/iOS implementations
└── api/
    ├── rest_api/                # External integrations
    ├── websocket/               # Real-time communications
    └── sdk/                     # Developer toolkit
```

Process Flow Architecture

```
Event Sources → Platform Abstraction → Detection Engine → Response Engine → Logging/Reporting
    ↓              ↓                    ↓                ↓                ↓
Network Logs    OS Abstraction      Pattern Match     Auto-Response    Evidence Chain
System Events   API Normalization   ML Analysis       Containment      Compliance
User Activity   Resource Access     Risk Scoring      Notification     Analytics
```

---

2. ABSTRACTED ENGINE DESIGN

Core Engine Interface

python

```python
from abc import ABC, abstractmethod
from typing import Dict, List, Any, Optional
from dataclasses import dataclass
from enum import Enum

class ThreatLevel(Enum):
    LOW = "low"
    MEDIUM = "medium"
    HIGH = "high"
    CRITICAL = "critical"

@dataclass
class SecurityEvent:
    event_id: str
    timestamp: datetime
    source: str
    event_type: str
    data: Dict[str, Any]
    threat_level: ThreatLevel
    platform: str

@dataclass
class ResponseAction:
    action_type: str
    target: str
    parameters: Dict[str, Any]
    timeout: int
    rollback_available: bool

class SecurityModule(ABC):
    """Base class for all security modules"""

    @abstractmethod
    def initialize(self, config: Dict[str, Any]) -> bool:
        pass

    @abstractmethod
    def process_event(self, event: SecurityEvent) -> Optional[ResponseAction]:
        pass

    @abstractmethod
    def get_health_status(self) -> Dict[str, Any]:
        pass

class PlatformAdapter(ABC):
    """Platform-specific implementation interface"""
```

```python
    @abstractmethod
    def get_system_events(self) -> List[SecurityEvent]:
        pass

    @abstractmethod
    def execute_response(self, action: ResponseAction) -> bool:
        pass

    @abstractmethod
    def get_system_capabilities(self) -> List[str]:
        pass
```

Modular Engine Core

```python
class SecurityEngine:
    def __init__(self, platform_adapter: PlatformAdapter):
        self.platform = platform_adapter
        self.modules: Dict[str, SecurityModule] = {}
        self.event_pipeline = EventPipeline()
        self.response_orchestrator = ResponseOrchestrator()
        self.config_manager = ConfigurationManager()

    def register_module(self, name: str, module: SecurityModule):
        """Dynamic module registration"""
        if module.initialize(self.config_manager.get_module_config(name)):
            self.modules[name] = module

    def process_security_events(self):
        """Main processing loop"""
        events = self.platform.get_system_events()

        for event in events:
            # Process through all registered modules
            responses = []
            for module in self.modules.values():
                response = module.process_event(event)
                if response:
                    responses.append(response)

            # Orchestrate responses
            self.response_orchestrator.execute_responses(responses)
```

Platform Abstraction Layer

python

```python
class PlatformFactory:
    """Factory for platform-specific adapters"""

    @staticmethod
    def create_adapter() -> PlatformAdapter:
        system = platform.system().lower()

        if system == "windows":
            return WindowsAdapter()
        elif system == "linux":
            return LinuxAdapter()
        elif system == "darwin":
            return MacOSAdapter()
        elif AndroidDetector.is_android():
            return AndroidAdapter()
        else:
            return GenericAdapter()

class WindowsAdapter(PlatformAdapter):
    def get_system_events(self) -> List[SecurityEvent]:
        # Windows Event Log parsing
        # WMI queries
        # Performance counters
        pass

    def execute_response(self, action: ResponseAction) -> bool:
        # Windows Firewall API
        # Service control
        # Registry modifications
        pass

class LinuxAdapter(PlatformAdapter):
    def get_system_events(self) -> List[SecurityEvent]:
        # journalctl parsing
        # /proc filesystem monitoring
        # netlink sockets
        pass

    def execute_response(self, action: ResponseAction) -> bool:
        # iptables/nftables
        # systemctl operations
        # cgroup management
        pass
```

4. FRAMEWORK EXTENSIBILITY POINTS

Future Module Integration Points

1. **Threat Intelligence Feeds**
   - STIX/TAXII integration
   - Custom threat feeds
   - IoC management
2. **Advanced Analytics**
   - Machine learning pipelines
   - Behavioral modeling
   - Anomaly detection
3. **Compliance & Reporting**
   - SOC 2 compliance
   - GDPR/HIPAA reporting
   - Custom audit trails
4. **Integration Ecosystem**
   - SIEM connectors
   - SOAR platform integration
   - Cloud security platforms

Configuration-Driven Architecture

```yaml
```

```yaml
# engine_config.yaml
engine:
  platform: auto-detect
  max_threads: 10
  event_buffer_size: 10000

modules:
  network_security:
    enabled: true
    config:
      monitor_interfaces: ["eth0", "wlan0"]
      detection_threshold: 100

  endpoint_security:
    enabled: true
    config:
      file_monitoring: true
      process_monitoring: true

platform_overrides:
  windows:
    event_sources: ["Security", "Application", "System"]
  linux:
    event_sources: ["/var/log/syslog", "journald"]
```

---

5. IP PROTECTION STRATEGY

Code Protection Mechanisms

1. **Core Engine Obfuscation**
   - Critical algorithms protected
   - License key validation
   - Runtime integrity checks
2. **Module Encryption**
   - AES-256 module encryption
   - Signed module verification
   - Tamper-proof deployment
3. **API Key Management**
   - Hardware-based key storage
   - Time-limited licenses

- Usage analytics

Deployment Architecture

```
┌─────────────────┐   ┌─────────────────┐   ┌─────────────────┐
│ Protected Core  │   │ Licensed        │   │ Open Interface  │
│ (Proprietary)   │──▶│ Modules         │──▶│ (Customer API)  │
│ KK&G IP         │   │ (Encrypted)     │   │ (Documented)    │
└─────────────────┘   └─────────────────┘   └─────────────────┘
```

---

6. ENTERPRISE INTEGRATION PATTERNS

Deployment Models

1. **Standalone Agent**
   - Single-host protection
   - Local configuration
   - Offline operation capable
2. **Centrally Managed**
   - Enterprise console
   - Policy distribution
   - Centralized logging
3. **Cloud-Native**
   - Container deployment
   - Auto-scaling
   - Managed service integration

Performance Characteristics

- **Memory footprint**: < 50MB base engine
- **CPU overhead**: < 5% on idle, < 20% during events
- **Network overhead**: Configurable, bandwidth-aware
- **Storage**: Rotating logs, configurable retention

This framework provides the enterprise-grade foundation for your cybersecurity engine while maintaining modularity, cross-platform compatibility, and IP protection.
